EDITION DIRECTION

Connect an Outcome to the Work That Produced It

An intended Standard edition for requirements, controlled protocols, attributed actions and evaluation of AI-assisted work.

The design asks a practical question: can a reviewer determine what was required, what changed, who acted and why an outcome was accepted?

Traceability would apply Standard's industry-specific record approach to that chain of evidence. Research explores the architecture; product design must define the usable workflow and its operating limits.

This edition is in design. The research is not evidence of an available customer release.

A PROPOSED EVALUATION RECORD

Keep the Requirement Beside the Decision

The intended value is a retrievable explanation of the decision. Specific integrations, controls and acceptance criteria remain design work.

Requirement

State what the work must achieve and the conditions under which its result will be evaluated.

Protocol

Identify the method, authorized actors and evidence required to perform the work.

Attribution

Connect actions and changes to their source, version and operating context.

Evaluation

Record the result against the requirement and the reasons for acceptance, rejection or further investigation.

DESIGN PARTNER INVITATION

Start With a Consequential Decision

Bring a process where the evidence must survive review.

Choose the Process	Identify its users, requirements, important decisions and the evidence retained today.
Expose the Gaps	Show where version changes, missing attribution or incomplete evaluation make the outcome difficult to explain.
Define the Target	Agree the proposed record, access boundaries, review method and a practical acceptance example.

The Inference Traceability paper provides research context. A design engagement would establish the proposed product scope and terms separately.
