METRASLATE

PRODUCT OVERVIEW / OCTOBER 2026

Software for the assets. Software for the business.

A detailed guide to Standard, Asset and the connected MetraSlate product family.

Know what equipment you have, what work needs doing, who is responsible and what the customer owes. Carry that information from the first request to the completed job and the financial record.

CUSTOMER ACCOUNT / STANDARD

Monthly recall planning, sites and connected customer records. Actual application capture with sample data.

STANDARD **ASSET** **ASSET LIGHT**

01 / PRODUCT FAMILY

Choose the starting point. Keep the business connected.

MetraSlate is the company. Standard runs the business through industry-specific workflows. Asset combines asset management with end-to-end business operations. Asset Light provides asset management without the business operations.

Standard	Runs the business from leads and estimates through work, documents, delivery, invoicing and accounts receivable. Industry editions adapt the work records, terminology and specialist tools.
Standard: Metrology	The first industry edition. Adds laboratory workflows: structured calibration data, reference standards, uncertainty, review, certificates and quality records, connected to the commercial job.
Asset	Starts with equipment ownership and lifecycle management, and extends across the business that owns or manages those assets. It includes the operational context around an asset, rather than treating the asset register as a standalone spreadsheet.
Asset Light	Manage equipment records, locations, custody, maintenance and calibration due dates, service history and documents. Asset Light leaves out the CRM, invoicing, accounting and wider business operations included in Asset.

Related products being developed

Metrologistics is the planned marketplace for equipment and services. Equipment owners describe the required work, find suitable providers, compare quotes and agree service or equipment transactions. **MetraSocial** is the planned professional community: build a profile, find peers, join relevant conversations and share practical resources that other people can find and use again.

Practical distinction: Asset manages equipment and the business around it. Asset Light manages the equipment without business operations. Customer portals provide a related access surface where a service provider shares work information and documents with its customers.

02 / CUSTOMER TO CASH

Follow one job from request to payment.

For a calibration laboratory, the customer's requirements should remain attached to the instruments, the work and the invoice. Each department contributes to the same job.

1. Understand the request	Sales records the customer, site, contact, instruments, requested service and target date. An opportunity tracks the commercial discussion and the next action.
2. Price and agree	Create an estimate with priced lines and agreed scope. Keep revisions under the same estimate history. Record approval or decline, customer notes and a purchase-order reference.
3. Receive and assign	Convert accepted work into a work order. Identify the actual instruments received, record custody and assign the lines to the appropriate people. Different items can progress at different speeds.
4. Perform and review	Technicians complete the required procedure and readings. Reviewers examine the result and supporting evidence. An item awaiting parts or a customer answer keeps its own status.
5. Release and deliver	Release the certificate or other required document, then coordinate shipment, pickup or delivery. Keep the released document connected to its equipment and job.
6. Invoice and Record Payment	Create the invoice from the work and agreed prices. Apply receipts and credits to the financial records. The office can trace an invoice line back to the work it represents.

The information is useful because it changes the next action

A late item identifies work that needs attention. A quote awaiting approval belongs with the person who follows up. An instrument due next month supports planning. A financial total leads to the invoices behind it. Teams should not need to reconstruct the story from separate spreadsheets and conversations.

03 / STANDARD METROLOGY

The measurement and the business record belong together.

The Metrology Edition supports the technical work of a calibration laboratory and the evidence reviewers and customers need after the instrument leaves the bench.

Prepare the work once

Asset templates describe a type of equipment and its specifications. Procedures and structured datasheets define the work technicians need to perform. The job identifies the customer's actual instrument, the required service and the standards used for that calibration.

Technician	Record readings and the applicable units, tolerance, conditions and reference standards. Capture as-found and as-left results where the procedure requires them, so adjustment does not erase the original condition.
Technical reviewer	Inspect readings, calculations, uncertainty and the applicable decision rule. Confirm the required evidence before authorizing release, rather than relying on a completed status alone.
Quality team	Investigate a nonconformance, identify affected work, record disposition and corrective action, and retain ownership and closure conditions. Keep controlled documents and their revisions available to the people doing the work.
Customer	Receive the released certificate connected to the instrument and service history. The record remains understandable when the customer needs it for an audit, equipment decision or subsequent service.

Documents are generated from the work

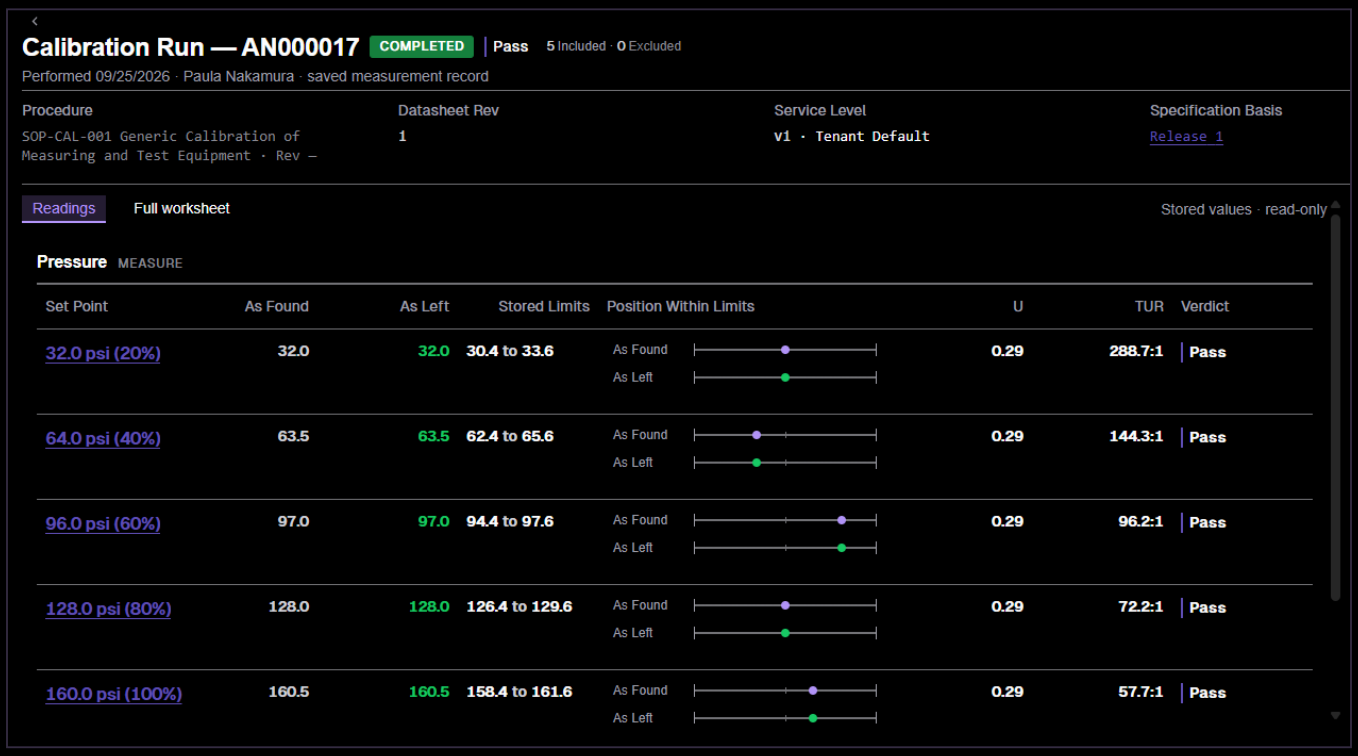

Document Creator provides reusable templates with fields bound to record data and repeating tables for results. Templates can be previewed, validated, versioned and activated. Finalized calibration records preserve the recorded basis of the result; correction history preserves the predecessor rather than silently replacing it.

Example: a customer's digital multimeter arrives for calibration. Its work-order line identifies the service, the technician records the required points against reference standards, a reviewer checks the evidence, and the released certificate stays linked to that exact instrument and invoice.

IN THE PRODUCT / CALIBRATION

Read the measurement. Keep its context.

The calibration record connects each measurement point to the instrument and its result. Technical evidence remains useful after the bench work is complete.

Completed calibration record, readings detail. The capture shows set points, as-found and as-left values, position within stored limits, uncertainty and verdicts. Sample data.

Instrument and procedure

The heading identifies the instrument and completed run. The procedure and datasheet revision provide the recorded basis for the measurement work.

Readings and decisions

The technician and reviewer can examine individual points rather than relying only on a final pass result. Each row preserves the values associated with that point.

Connected documentation

The completed record is the source for technical review and the resulting certificate. Supporting standards and environmental context belong to the same calibration.

04 / ASSET

Manage every asset. Run the business around it.

Asset is asset management software and end-to-end software for running the business. Its purpose is to connect the equipment lifecycle to the work, people, customers, suppliers and financial decisions surrounding it.

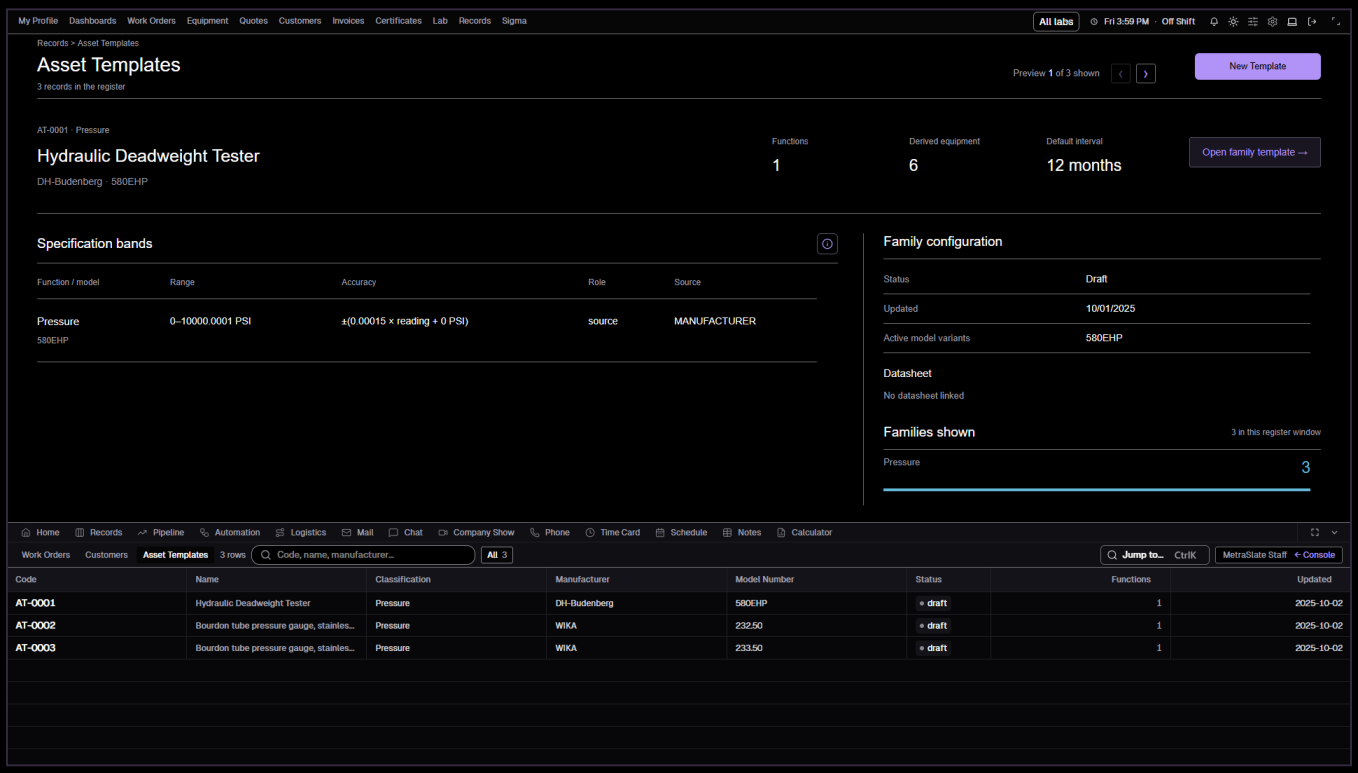

Identify and locate	Maintain individual asset records with identifiers, manufacturer and model, serial number, ownership, site, location and supporting documents. Reuse asset templates for equipment of the same type.
Plan service	Track required maintenance, calibration and other service dates. See work coming due by period and location, prioritize overdue equipment, and prepare service requests before equipment becomes unavailable.
Control movement	Record where equipment is and who has custody. Connect transfers, checkout, return, outside service and other events to the equipment history instead of relying on someone's memory.
Do the work	Connect assets to work orders, assignments, maintenance and service records. Preserve the outcome, documents and next due date with the individual asset.
Manage the business	Bring customer records, estimates, purchasing, inventory, scheduling, communications and financial records into the operation. An asset is part of a business process, not an isolated inventory entry.
Make lifecycle decisions	Review service history, availability, recurring issues and recorded costs to decide whether an asset should return to use, receive more work or be replaced.

Example: a company operates instruments across several sites. The coordinator identifies next month's due equipment, arranges service, tracks each instrument's location, receives the resulting documents and reviews the related purchasing and cost records. The same company can manage its wider operational work in Asset.

IN THE PRODUCT / EQUIPMENT

Describe the equipment once. Use it across individual assets.

An asset template holds the common model and service information for equipment of the same type. Individual equipment records retain their own identity and history.

Asset Templates in Standard. A sample pressure-instrument family displays its specification, default interval and derived equipment alongside the template register.

Reusable model information

Manufacturer, model, function, range and accuracy describe what the equipment is. A reusable template gives individual units a consistent starting point.

Individual equipment history

Serial number, location, custody, service dates and completed work belong to the actual unit. Shared specifications do not replace its individual service history.

Asset and Asset Light

Both product definitions center on this equipment lifecycle. Asset adds end-to-end business operations; Asset Light focuses on asset management without those operations.

05 / OPERATIONS AND MONEY

Connect the physical work to purchasing and finance.

A job is not finished when the technician is finished. Materials, outside services, equipment movements, invoices and payments still need owners and records.

Purchasing and receiving	Keep supplier orders and received items connected to the need they fulfill. Purchasing can see what has been ordered and received; operating teams can understand what is still holding up the work.
Inventory and rentals	Maintain inventory-item records and the transactions affecting them. Rental records connect equipment checkout and return to the customer and related commercial work.
Pickup and delivery	Organize logistics as records: pickups, deliveries, routes and handovers. Give drivers the relevant stops and give the office a history of where equipment moved.
Invoices and receipts	Raise invoices from work-order lines, preserve the agreed pricing history, record receipts against invoices and handle credit memos. A payment may be allocated across several invoices.
Books and reconciliation	Use the chart of accounts and journal alongside the operational documents. Reconcile bank statements, manage accounting periods and follow the entries associated with business transactions.
Management reporting	Review workload, due work, financial exposure and other operating results. Open the contributing records where the view supports it, so a number can be investigated and acted on.

One example across departments

An instrument needs an external repair. The office records the customer decision; purchasing arranges the outside work; operations tracks custody and receipt; the technician completes the remaining service; and finance invoices the agreed work. The customer, instrument and work order provide the common reference throughout.

Configuration and implementation define the organization's accounting treatment, approval responsibilities and external-system boundaries. Payroll and jurisdiction-specific tax requirements are scoped separately.

06 / PEOPLE AND CUSTOMERS

Give each person the information for their part.

Different people need different views of the same operation. Customer access, internal collaboration and staff responsibilities should remain connected to the records they concern.

Customer service	See the customer account, contacts, equipment, open work and conversation history together. A customer question can be handled with the actual job and its current position in view.
Technicians and reviewers	Work from assignments and relevant records, with qualifications and permissions governing responsibilities. Scheduling and time records help connect people to the work they perform.
Managers	Review workload and exceptions across the organization, region or site where applicable. Investigate the records behind a result instead of treating a dashboard as a separate presentation.
Asset Light users	Manage equipment identity, location and custody. Plan maintenance and calibration from due dates, and retain service history and documents without adopting the wider business-operation tools.
Customers in the portal	View the equipment, work progress and released documents shared with their account. Participate in service requests and approvals through a customer-facing access surface connected to the provider.
Administrators	Manage access and configuration for their organization. Separate customer access, operating roles and platform administration, so a shared application does not mean shared permission to every record.

Communications should have context

Chat, mail and customer-service conversations belong beside the relevant customer and work. Phone workflows are intended to connect incoming calls, account identification, call history and follow-up to that same customer context. Mail, calling and SMS depend on the organization's configured service connections.

Follow-up should be configurable

The survey workflow is designed to use automation for follow-up after service or a call, with configurable questions and delivery channels. For example, a later contact can ask whether the customer called about the same issue. Survey responses support service improvement and resolution reporting; delivery and reporting are configured as part of the rollout.

07 / CONFIGURATION AND REPORTING

Adapt the process to the company using it.

Customers need their own roles, records, documents and operating rules. Configuration should make those differences explicit without breaking the connections between departments.

Workflow automation	Define an event, its conditions and the action that follows. Publish a workflow, maintain its changes and inspect execution history. Examples include routing an approval or notifying the next responsible person.
Documents	Create reusable certificates and business documents. Bind record fields, populate repeated rows, inspect a preview and activate a version. A template change should have an identifiable version.
Asset templates	Describe common equipment once and reuse it for individual units. Templates provide a consistent basis for specifications and the associated service work.
Sigma reporting	Use available reports or compose a report around an operational question. Set filters, preview results and share the report with the people who need it.
Roles and access	Assign privileges and responsibilities to people. Customer-facing access remains scoped to the customer; internal users see the areas their role permits.
Company structure	Represent the customer's organization and sites so work, equipment and reporting can be understood at the level where decisions are made.

Make the configuration serve an actual decision

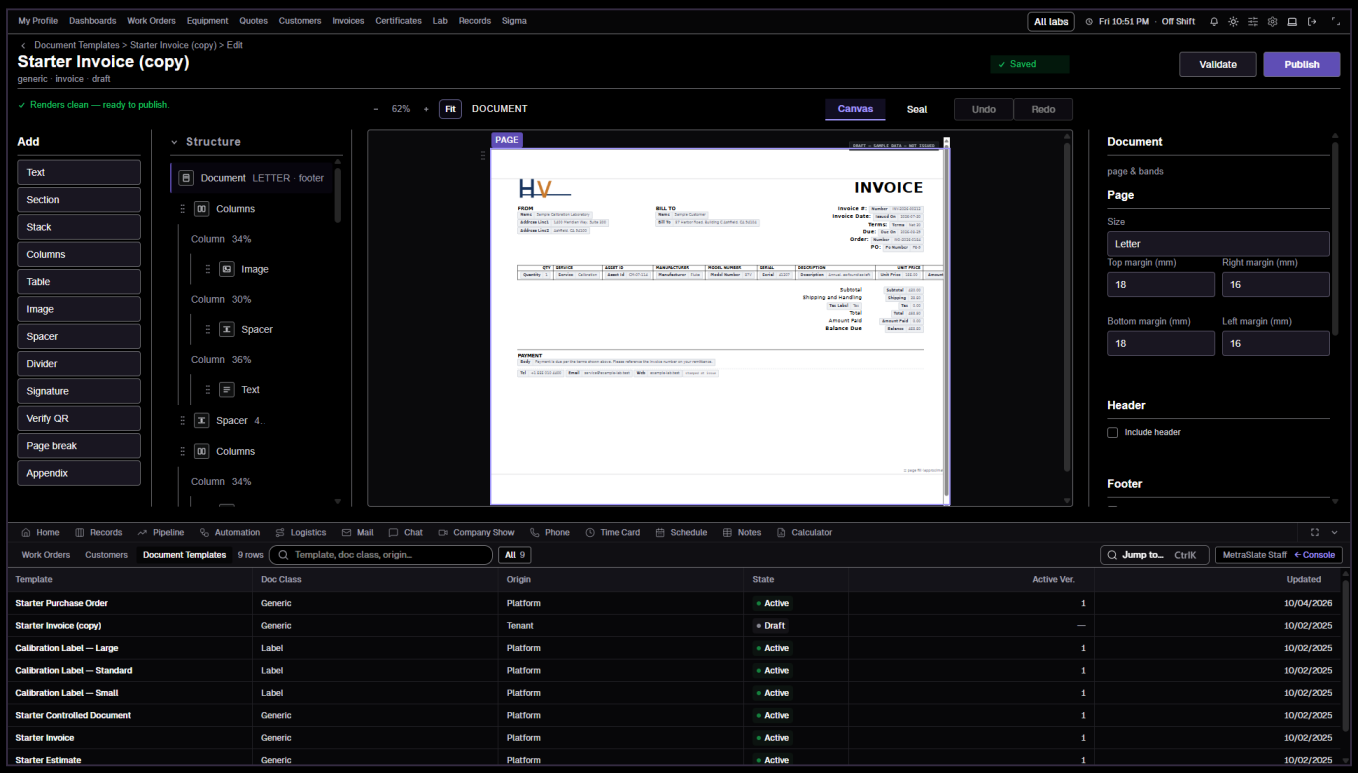

A useful recall view answers which equipment needs service and when. A useful workload view identifies the next action and responsible person. A useful invoice view explains what is outstanding and why. Reports, dashboard cards and notifications should support those decisions rather than repeat the same totals in several places.

Implementation principle: agree the operating rules with the customer, test them with a representative job and its exceptions, then make those rules visible in the workflow, permissions, documents and reports.

IN THE PRODUCT / DOCUMENT CREATOR

Make the document part of the workflow.

Document Creator lets the organization compose reusable documents around record data, inspect the result and manage publication of the template.

Document Creator in Standard. A sample invoice template is open with its structure, page preview, document settings and validation and publishing controls.

Structure and data

Arrange sections, tables, text and other elements into a reusable document. Bound record fields and repeating rows carry business information into the output.

Preview before publication

Inspect the page and its configuration in the same workspace. The template has its own saved state and publication steps.

Useful beyond one document

Use the same approach for certificates and other business documents. Versioned templates let the organization control the format it issues to customers.

08 / GETTING STARTED

Start with a real workflow. Carry the details through.

The best product demonstration follows a recognizable job, with the customer's actual records and responsibilities in mind. It should show how the operation works, not just a collection of screens.

1. Define the operation	Identify the business, its sites, its equipment and the people who sell, perform, review, deliver and bill the work. Select Standard or Asset around that operating need.
2. Choose the example	Bring one representative customer request and the equipment involved. Include an exception such as an approval delay, repair, partial shipment or corrected document.
3. Map the records	Identify current customer, equipment, supplier, work and document data. Decide what is migrated, what is retained as history and who validates the imported records.
4. Configure the process	Set access, responsibilities, templates, workflow steps and required service connections. Agree the records and reports each team needs.
5. Walk the complete job	Demonstrate the request, estimate, receipt, work, review, release, delivery and financial outcome. Confirm what the customer sees and what each internal role can do.
6. Roll out with ownership	Agree onboarding, support, deployment and operating responsibilities. Expand from the validated workflow to the rest of the customer's operation.

What to bring to the conversation

A sample asset list, a typical estimate or work order, a released document, the main approval steps, the systems currently used and the handoffs that create the most delay. Sensitive examples can be replaced with representative data.
